

# 2011 International Conference on Ecology & Transportation

August 21-25 • Seattle, Washington, USA

Conference Proceedings

## Sustainability in Motion

**CTE**

Organized and Co-sponsored by the  
Center for Transportation and the  
Environment

Co-hosted by the Washington State  
Department of Transportation

## **Acknowledgements**

These proceedings of ICOET 2011 are published by the Center for Transportation and the Environment (CTE), located at the Institute for Transportation Research and Education (ITRE), North Carolina State University (NCSSU), with additional funding support provided by the U.S. DOT Federal Highway Administration, U.S. Forest Service, U.S. Environmental Protection Agency, Washington State Department of Transportation, University of California at Davis, Western Transportation Institute at Montana State University, Defenders of Wildlife, and various co-sponsor organizations.

CTE thanks the following persons and organizations for their assistance with this publication:

- Paul Wagner, Washington State Department of Transportation, ICOET 2011 Conference Chair; Debra Nelson, New York State Department of Transportation, ICOET 2011 Program Committee Chair; and members of the ICOET 2011 Steering, Program, and Abstract Review Committees; whose hard work and dedication to the field of transportation and ecology generated an excellent technical program for the conference, the results of which are reflected in these proceedings.
- The many staff of the Washington State Department of Transportation who co-hosted the conference, designed the field trips, moderated technical sessions, and prepared presentations showcasing the state's outstanding research and partnership-building efforts.
- CTE staff Ann Hartell, Nancy Bailey, and Walt Thomas who assisted greatly in developing and organizing the conference program, compiling presenter materials, and in review and distribution of this document.
- Most importantly, to all the Authors who, in contributing their work to these conference proceedings, have expanded the body of knowledge on wildlife, habitat, and ecosystem issues related to the delivery of surface transportation systems.

Please note that these proceedings are not a peer-reviewed publication. The research presented herein is a compilation of the technical papers and posters selected for presentation at the 2011 International Conference on Ecology and Transportation. Presentations were selected by the ICOET 2011 Program Committee based on a set of criteria that included relevance to the conference theme and applicability of research results. Presentations included in this document may be in full paper or abstract format. Contact information for the authors is provided where possible to encourage further networking among conference participants and other professionals about current research applications and best practices in the transportation/ecology field.

### **Bibliographic Citation**

Please use the following format to cite works from these proceedings:

[Author last name, first name]. ["Title of Paper"]. In *Proceedings of the 2011 International Conference on Ecology and Transportation*, edited by Paul J. Wagner, Debra Nelson, and Eugene Murray. Raleigh, NC: Center for Transportation and the Environment, North Carolina State University, 2012.

### **Cost Statement**

CD-ROM copies of this public document are duplicated on demand for an approximate cost of USD \$5.00 per unit and are distributed to conference participants upon individual request. No printed copies of the document were produced.

### **To Order Copies**

An Adobe Acrobat PDF version of these proceedings is available free for download from the ICOET website at [www.icoet.net](http://www.icoet.net). CD-ROM copies of the proceedings may be ordered through CTE for USD \$25.00 including shipping and handling. To order, please call CTE at (919) 515-8893 or email your request to [cte\\_email@ncsu.edu](mailto:cte_email@ncsu.edu).

### ABSTRACT

Animal-vehicle collisions affect human safety, property, and wildlife, and the number of animal-vehicle collisions has increased in many regions across North America. Animal detection systems can help reduce the number of wildlife-vehicle collisions and allow for safe crossing opportunities for wildlife. These systems detect large animals when they approach the road and once a large animal has been detected, warning signs are activated. Drivers can then respond by becoming more alert, reducing the speed of their vehicle, or both. For animal detection systems to be effective in reducing collisions, reliable systems are essential. For a previous project we investigated the reliability of nine systems from five manufacturers. The current study reports on the reliability of two new systems: 1. a buried cable that detects changes in an electromagnetic field when large animals walk over the cable and 2. a third generation break-the-beam system that uses microwave radio signals. The systems were investigated for their reliability in a controlled access test facility near Lewistown, Montana. The two new systems were also installed along real roadsides; the buried cable system was installed along Hwy 160 near Durango, Colorado, and the microwave radio signal break-the-beam system was installed along Hwy 3 near Fort Jones, California. At the test facility near Lewistown, Montana, we used horses, llamas, and sheep as a model for wild ungulates. The animals roamed in an enclosure and data loggers recorded the date and time of each detection for both systems. Animal movements were also recorded by six infrared cameras with a date and time stamp. By analyzing the images and the detection data in different seasons, researchers were able to investigate the reliability for each system. The percentage of false positives (i.e., a detection is reported by a system but there is no large animal present in the detection zone) was relatively low for both systems ( $\leq 0.5\%$ ). However the percentage of false negatives (i.e., an animal is present in the detection zone but a system failed to detect it) differed substantially (1.9-16.8%). The percentage of intrusions (i.e., animal intrusions in the detection area) that were detected also varied substantially (88.6-99.5%). The results suggest that one of the two detection systems was quite reliable in detecting large mammals with few false positives and false negatives, whereas the other system had relatively many false negatives, mostly because of downtime. When we compared the reliability data to the recommended performance requirements that were obtained through interviews with three stakeholder groups we found that one of the two systems tested met the recommended requirements, while the other did not. Based on the results we know that some systems are quite reliable and may be considered for implementation along a roadside where they can be investigated for their effectiveness in reducing collisions with large wild mammals. However, experiences with installation, operation and maintenance suggest that the robustness of animal detection systems may have to be improved before the systems can be deployed on a large scale.

### INTRODUCTION

Animal-vehicle collisions affect human safety, property, and wildlife, and the number of animal-vehicle collisions has been increasing in many regions across North America (Huijser et al. 2007). Here we investigate a relatively new mitigation measure aimed at reducing animal-vehicle collisions while allowing animals to continue to move across the landscape. We evaluated the reliability of a range of different animal detection technologies from different manufacturers.

Animal detection systems detect large animals (e.g., deer (*Odocoileus* spp.), pronghorn (*Antilocapra americana*), elk (*Cervus elaphus*) and moose (*Alces alces*)) as they approach the road (see reviews in Huijser et al. 2006; 2009a). When an animal is detected, signs are activated, warning drivers that large animals may be on or near the road at that time. Previous studies have shown variable effects of activated warning signs on vehicle speed: substantial decreases in vehicle speed ( $\geq 5$  km/h ( $\geq 3.1$  mi/h)) (Kistler 1998; Muurinen and Ristola 1999; Kinley et al. 2003; Gagnon et al. 2010); minor decreases in vehicle speed ( $< 5$  km/h ( $< 3.1$  mi/h)) (Kistler 1998; Muurinen and Ristola 1999; Gordon and Anderson 2002; Kinley, et al. 2003; Gordon, et al. 2004; Hammond and Wade 2004; Huijser et al. 2009a); and no decrease or even an increase in vehicle speed (Muurinen and Ristola 1999; Hammond and Wade 2004). This variability of the results is likely related to various conditions (see review in Huijser et al. 2009a):

- The type of warning signal and signs.
- Whether the warning signs are accompanied with advisory or mandatory speed limit reductions.
- Road and weather conditions.
- Whether the drivers actually see an animal.
- Whether the driver is a local resident.
- Perhaps the road length of the zone with the animal detection system and the road length that the warning signs apply to (the more location specific the better).
- Perhaps also cultural differences that may cause drivers to respond differently to warning signals in different regions.

Activated warning signs may also result in more alert drivers, which can lead to a substantial reduction in stopping distance: 20.7 m (68 ft) at 88 km/h (55 mi/h) (review in Huijser et al. 2009a). Finally, research from Switzerland has shown that animal detection systems can reduce ungulate-vehicle collisions by as much as 82 percent (Mosler-Berger and Romer 2003). In Germany collisions with large mammals were reduced by more than 80% (Strein 2010). In Montana a reduction of 58% was recorded (Huijser et al. 2009a) and data from Arizona showed a reduction of 97 percent (Gagnon et al. 2010).

Before animal detection systems can be effective, they must be able to detect large animals reliably. Therefore it is important to know how reliable animal detection systems are when detecting large animals and to establish minimum norms for system reliability. Until now, measuring and comparing the reliability of different animal detection systems has been problematic due to the following factors:

- Most systems have not been properly studied, or the results have not been published.
- Different studies have evaluated systems with regard to different parameters.
- Different studies used different methods.
- Different systems have been evaluated under varying conditions (e.g., varying road and climate conditions).

For a previous project we investigated the reliability of nine systems from five manufacturers (Huijser et al. 2009a; 2010). The current study reports on the reliability of two new systems: 1. a buried cable that detects changes in an electromagnetic field when large animals walk over the cable and 2. a third generation break-the-beam system that uses microwave radio signals. The systems were investigated for their reliability in a controlled access test facility near Lewistown, Montana. The two new systems were also installed along real roadsides; the buried cable system was installed along Hwy 160 near Durango, Colorado, and the microwave radio signal break-the-beam system was installed along Hwy 3 near Fort Jones, California. At the test facility near Lewistown, Montana, we used horses, llamas, and sheep as models for wild ungulates.

## **METHODS**

### **Test-bed location**

The RADS test-bed is part of the TRANSCEND cold region rural transportation research facility and is located along a former runway at the Lewistown Airport in central Montana (Fig. 1). The test-bed location experiences a wide range of temperatures, and precipitation ranges include mist, heavy rain, and snow; the topography is flat, and the rocky soil does not sustain much vegetation that may obstruct the signals transmitted or received by the sensors. The test-bed consists of an animal enclosure, the two animal detection systems, and six infrared cameras with continuous recording capabilities (Fig. 2). The distance covered was 50 m (164 ft) for buried cable system and 91 m (300 ft) for the microwave radio signal break-the-beam system (from the left to the right side of the enclosure).

**Figure 1.** The location of the test-bed along a former runway at the Lewistown Airport in central Montana. The current municipal airport is located on the upper right of the photo.

**Figure 2.** Test-bed design including an animal enclosure, the two detection systems (open circles = poles for sensors), the six infrared cameras aimed at the enclosure from the side (solid circles), and the office with data recording equipment. Arrows show the direction of transmitter.

## Animal Detection Systems and Data Recording Equipment

The first system tested is a buried cable (Perimitrax®) that detects large mammals when they move across the cable (Table 1). The system is manufactured by Senstar Corporation, Carp, Ontario, Canada, and it is the exact same technology as originally installed along US Hwy 160 near Durango, CO, USA. The buried cable was placed in a trench and wrapped in sand and geotextile nine inches below the surface. The system was installed in Lewistown on 11 and 12 August 2009. The system generates an invisible electromagnetic field and when a large animal crosses the cable it causes a disturbance in this electromagnetic field. The electrical conductivity, size and speed of the animal all affect the magnitude of the disturbance. However, the threshold that needs to be met to declare an "alarm" or "detection" is adjustable and can be set depending on the size of the animal one wishes to detect. Detection messages are transmitted to a computer in the research trailer at the test-bed where they are saved in files for later analysis.

The second system tested is a microwave radio signal break-the-beam system manufactured by ICx Radar Systems (Scottsdale, Arizona (formerly Sensor Technologies and Systems, Inc.) (Table 1). The system is the third generation of this detection technology (RADS III). Previous generations (RADS I and RADS II) were evaluated for their reliability in an earlier project (Huijser et al. 2009b). The RADS III is the exactly the same detection technology as was installed along Hwy 3 near Fort Jones, CA, USA. The system was installed in Lewistown, MT on 16 December 2009. The center of the beam was set at about 73.7 cm (29 inches) above the ground. However, because of rises and depressions in the terrain, the center of the beam was estimated to have varied between 71.1 and 76.2 cm (28-30 inches) above the ground. Setting the center of the beam lower may have resulted in false positives as a result of the grass-herb vegetation in the enclosure.

**Table 1. The characteristics of the two animal detection systems.  
See appendix A for manufacturer contact details.**

| Manufacturer and system name | System type    | Signal type                       | Maximum range        | Installation date |
|------------------------------|----------------|-----------------------------------|----------------------|-------------------|
| Magal Senstar (Perimitrax®)  | Buried cable   | Electromagnetic field             | About 0.1 mi (161 m) | 11/12 Aug 2009    |
| STS (RADS III)               | Break-the-beam | Microwave radio ( $\pm$ 35.5 GHz) | About 1/2 mi (804 m) | 16 Dec 2009       |

Six infrared cameras (Fuhrman Diversified, Inc.) were installed perpendicular to the detection system. These cameras and a video recording system record all animal movements within the enclosure continuously, day and night. The two systems saved individual detection data with a date and time stamp in data logs. These data were compared to the images from the infrared cameras, which also had a date and time stamp, allowing the researchers to investigate the reliability of the system. Orange cones marked the location of the cable (first system) and the beam (second system) on the images.

### Wildlife Target Species and Models

In a North American setting, animal detection systems are typically designed to detect white-tailed deer (*Odocoileus virginianus*) and/or mule deer (*Odocoileus hemionus*), pronghorn (*Antilocapra americana*), elk (*Cervus elaphus*) or moose (*Alces alces*). In Montana, it is not legal to have deer, elk or moose in captivity. Therefore the researchers used domesticated species as a model for wildlife. For this study, which took place within an enclosure, two horses, two llamas, and two sheep were used as models for these wildlife target species. Horses are similar in body shape and size to moose, llamas represent deer and elk, and sheep represent small deer (Tables 2 and 3). The body size and weight of the individual horses, llamas, and sheep used in this experiment are shown in Table 4.

**Table 2. Height and length of wildlife target species and horses, llamas, goats and sheep.**

| <b>Species</b>        | <b>Height at shoulder</b> | <b>Length (nose to tip tail)</b> | <b>Source</b>                     |
|-----------------------|---------------------------|----------------------------------|-----------------------------------|
| <i>Target species</i> |                           |                                  |                                   |
| Moose                 | 6'5"-7'5" (195-225 cm)    | 6'9"-9'2" (206-279 cm)           | Whitaker (1997)                   |
| Elk                   | 4'6"-5' (137-150 cm)      | 6'8"-9'9" (203-297 cm)           | Whitaker (1997)                   |
| White-tailed deer     | 27-45" (68-114 cm)        | 6'2"-7' (188-213 cm)             | Whitaker (1997)                   |
| Mule deer             | 3'-3'5" (90-105 cm)       | 3'10"-7'6" (116-199 cm)          | Whitaker (1997)                   |
| Pronghorn             | 2'11"-3'5" (89-104 cm)    | 4'1"-4'9" (125-145 cm)           | Whitaker (1997)                   |
| <i>Models</i>         |                           |                                  |                                   |
| Feral horse           | 4'8"-5' (142-152 cm)      |                                  | Whitaker (1997)                   |
| Quarter horse         | 4'11"-5'4" (150-163 cm)   |                                  | UHS (2007), Wikipedia (2007)      |
| Llama                 | 3'-3'11" (91-119 cm)      |                                  | Llamapaedia (2007)                |
| Goat                  | 25"-30" (64-76 cm)        |                                  | ADM Alliance Nutrition Inc (2011) |
| Sheep                 | 25"-50" (63-127 cm)       |                                  | Minnesota Zoo (2011)              |

**Table 3. Body weight of wildlife target species and horses, llamas, goats and sheep.**

| <b>Species</b>        | <b>Weight male</b>        | <b>Weight female</b>      | <b>Source</b>                     |
|-----------------------|---------------------------|---------------------------|-----------------------------------|
| <i>Target species</i> |                           |                           |                                   |
| Moose                 | 900-1400 lbs (400-635 kg) | 700-1100 lbs (315-500 kg) | Whitaker (1997)                   |
| Elk                   | 600-1089 lbs (272-494 kg) | 450-650 lbs (204-295 kg)  | Whitaker (1997)                   |
| White-tailed deer     | 150-310 lbs (68-141 kg)   | 90-211 lbs (41-96 kg)     | Whitaker (1997)                   |
| Mule deer             | 110-475 lbs (50-215 kg)   | 70-160 lbs (32-73 kg)     | Whitaker (1997)                   |
| Pronghorn             | 90-140 lbs (41-64 kg)     | 75-105 lbs (34-48 kg)     | Whitaker (1997)                   |
| <i>Models</i>         |                           |                           |                                   |

**Table 4. Body size and weight of the horses, llamas, and sheep used in the experiment (Pers. com. Lethia Olson, livestock supplier). The measurements were taken in November 2010.**

| Individual        | Height at shoulder | Weight            |
|-------------------|--------------------|-------------------|
| Horse 1 (Bubba)   | 5' (152 cm)        | 1130 lbs (513 kg) |
| Horse 2 (Buster)  | 5'2" (157 cm)      | 1450 lbs (659 kg) |
| Llama 1 (Sparkle) | 3'9" (114 cm)      | 350 lbs (159 kg)  |
| Llama 2 (Cocoa)   | 3'9" (114 cm)      | 470 lbs (213 kg)  |
| Sheep 1           | 2'4" (71 cm)       | 170 lbs (77 kg)   |
| Sheep 2           | 2'5" (74 cm)       | 225 lbs (101 kg)  |

### Test periods

In 2009 and 2010 there were four ten day test periods with animals:

- Test period 1: Start on November 19, 2009 (at midnight), end on November 28, 2009 (end at midnight).
- Test period 2: Start on December 17, 2009 (at midnight), end on December 26, 2009 (end at midnight).
- Test period 3: Start on July 30, 2010 (at midnight), end on August 8, 2010 (end at midnight).
- Test period 4: Start on September 2, 2010 (at midnight), end on September 11, 2010 (end at midnight).

For each test day (24 hours), the researchers selected three random one-hour-long sections of video for review (stratified random). This resulted in a total of 30 hours during which the reliability of the system was investigated for each test period, and 120 hours for the four test periods combined. The images from the time periods that were analyzed were all saved on DVD. Time periods that were not analyzed were not saved.

In addition, there were two ten day test-periods without domesticated animals present in the enclosure:

- Test period 1: Start on December 7, 2009 (at midnight), end on December 16, 2009 (end at midnight).
- Test period 2: Start on January 5, 2010 (at midnight), end on January 14, 2010 (end at midnight).

The detection data from these two periods were screened for the potential presence of detections (which may indicate false positives), and extreme environmental conditions (based on weather data from a nearby meteorological station). The researchers selected 10 hours from this ten day period for review. These hours were non-randomly selected based on potential suspicious detection patterns (i.e., detections were reported while there are no domesticated animals present), and extreme environmental conditions.

### Reliability Parameters

The time periods reviewed were analyzed for valid detections, false positives, false negatives, and intrusions in the detection area. These terms are defined below (see Huijser et al. 2009b for more details).

- *False positives* – A false positive was defined as “when the system reported the presence of an animal, but there was no animal in the detection zone.” Thus, each incident in which a system’s data logger recorded a detection, but there was no animal present in the detection zone of that system, was recorded as a false positive. The date and time were recorded for all false positives.
- *False negatives* – A false negative was defined as “when an animal was present but was not detected by the system.” However, due to animal behavior and the design of some detection systems (i.e., some systems are desensitized by the continuous presence of an animal), there are several ways for a false negative to occur. Therefore, various types of false negatives were distinguished and these were recorded separately.
- *Intrusions in detection area* – An intrusion was defined as “the presence of one or multiple animals in the detection zone.” An intrusion began when one or more animals entered the detection zone and ended when all animals left the detection zone.

We compared the reliability data to the recommended performance requirements that were obtained through interviews with three stakeholder groups (Huijser et al. 2009b).

## RESULTS

The percentage of false positives (i.e., a detection is reported by a system but there is no large animal present in the detection zone) was relatively low for both systems (Magal Senstar: 0%; STS: 0.41%). However the percentage of false negatives (i.e., an animal is present in the detection zone but a system failed to detect it) differed substantially (Magal Senstar: 1.9%; STS: 16.8%). The percentage of intrusions (i.e., animal intrusions in the detection area) that were detected also varied substantially (Magal Senstar 99.5%; STS: 88.6%). A comparison of the reliability data to the recommended performance requirements that were obtained through interviews with three stakeholder groups (Huijser et al. 2009b) showed that the Magal Senstar system met the recommended requirements, while the STS system did not (Table 5).

**Table 5. The reliability of the two systems in relation to the recommended minimum norms. The percentage of intrusions detected is similar, though not exactly the same as the complement of the percentage of false negatives (see Huijser et al. 2009b).**

| <b>Manufacturer and system name</b> | <b>Meets false positives (yes/no)</b> | <b>Meets false negatives (yes/no)</b> | <b>Meets intrusions detected (yes/no)</b> | <b>Meets overall recommended norms (yes/no)</b> |
|-------------------------------------|---------------------------------------|---------------------------------------|---|---|
| Magal Senstar (Perimitrax®)         | yes                                   | yes                                   | yes                                       | yes   |
| STS (RADS III)                      | yes                                   | no                                    | no  | no  |

## DISCUSSION AND CONCLUSION

The results of the reliability tests showed that the percentage of false positives was low for both systems. The percentage of false negatives was higher than the recommended minimum norm for the STS system though. The STS system also did not meet the suggested minimum norm for detection intrusions in the detection zone. The Magal Senstar system met all of the recommended performance requirements for reliability. However, experiences with installation, operation and maintenance with this system along Hwy 160 near Durango, Colorado, showed that this system may still have problems with the integration of different system components (Huijser et al. 2011). The robustness of this and other animal detection systems (see e.g. Huijser et al. 2009b) may have to be improved before the systems can be deployed on a large scale.

## BIOGRAPHICAL SKETCHES

**Marcel Huijser** received his M.S. in population ecology (1992) and his Ph.D. in road ecology (2000) at Wageningen University in Wageningen, The Netherlands. He studied plant-herbivore interactions in wetlands for the Dutch Ministry of Transport, Public Works and Water Management (1992-1995), hedgehog traffic victims and mitigation strategies in an anthropogenic landscape for the Dutch Society for the Study and Conservation of Mammals (1995-1999), and multifunctional land use issues on agricultural lands for the Research Institute for Animal Husbandry at Wageningen University and Research Centre (1999-2002). Currently Marcel works on wildlife-transportation issues for the Western Transportation Institute at Montana State University (2002-present) and he is a member of the Transportation Research Board (TRB) Committee on Ecology and Transportation.

**Tiffany Allen** received a MSc in ecology at Montana State University in Bozeman, MT in 2011, a BSc in fish and wildlife management from Montana State University in Bozeman, MT in 2006, and a BM in music theory from Furman University in Greenville, SC in 2004.

**Matt Blank** is an assistant research professor at the Western Transportation Institute and the Department of Civil Engineering at Montana State University. Matt earned his Master of Science and Ph.D. in Civil Engineering at Montana State University. He earned his Bachelor of Science in Geological Engineering at the University of Wisconsin-Madison. His research focuses on the interactions of roads and riparian corridors with an emphasis on aquatic connectivity.

**Mark Greenwood** is a tenured Associate Professor of Statistics in the Department of Mathematical Sciences at Montana State University in Bozeman, MT. He received a PhD in Statistics from the University of Wyoming in 2004. His research involves nonparametric and nonlinear statistical methods with applications in geosciences, ecology, neuroscience, and economics.

**Mr. Shaowei Wang** was a Research Engineer at WTI through 2010, where he focused on systems and software engineering, data mining and statistical analysis for transportation safety and road weather management, Geographic Information Systems (GIS), software, web, and multimedia development, and cost benefit analysis for engineering applications. He has extensive skills in system architecture design, prototyping, simulation, and modeling. Mr. Wang holds a Master's Degree in Industrial and Management Engineering from Montana State University. He is also a member of the International Council on Systems Engineering.

**Larry Hayden** has more than 20 years' experience as a Senior Design Engineer, specializing in telecommunications, radio frequency and microwave circuitry. He has a strong background in mechanical engineering issues, and excellent troubleshooting skills. He has extensive experience in private industry product development, including eight years at Ball Aerospace, where he developed components for telecommunications satellites. At the Western Transportation Institute, he has applied his technical expertise to the development of communication solutions for transportation research facilities, special events, transportation safety and a virtual traffic management center. Currently, Mr. Hayden serves as a Research Associate at the Western Transportation Institute where he focuses on the analysis and development of telecommunications systems for transportation applications.

**Mr. Mohammad (Ashkan) Sharafsaleh** is a Senior Research and Development Engineer with California PATH Program of UC Berkeley. He has multiple advanced degrees in engineering and has worked as a consultant in private sector as well as the assistant City Traffic Engineer for the City of Berkeley prior to joining PATH in 2002. At PATH, he has managed a variety of projects including Performance Measurement System (PeMS), ITS Decision Website, Construction of PATH's Intelligent Intersection Test-Bed, and Evaluation of Animal Warning System effectiveness. He has also contributed to a number of other PATH projects throughout the years. The examples of these projects include Intersection Decision Support, Vehicle-Infrastructure Integration, and Cooperative Intersection Collision Avoidance Systems. He has also vast experience dealing with cities, counties, and state institutions for deployment and field collection efforts.

## ACKNOWLEDGEMENTS

The authors would like to thank the Colorado Department of Transportation and the California Department of Transportation for initiating and supporting the projects on which this manuscript is based. The authors are particularly grateful to Brian Allery, Tony Cady, Kevin Curry, Vanessa Henderson, Jeff Peterson, Bryan Roeder, and Mike McVaugh (all from the Colorado Department of Transportation), Alison Deans Michael (US Fish and Wildlife Service), Allen Graber, Amanda Kuenzi, and Jana Sterling (all from SWCA Environmental Consultants), Samir Siouti (Senstar Corporation), and Lloyd Salsman for their help with installing the systems in the test-bed, Wicken's Construction for their help with system installation and modifications to the test bed, and Lethia Olson for supplying livestock.
